ABSTRACT

Many mechanical systems are inherently flexible, making it difficult to achieve rapid, controlled motion. The control challenge is even greater when the system is not well modelled, has dynamics that change with time, or is under-actuated. A rocket with sloshing fluid propellant is an extreme case. Many control strategies struggle with such systems. However a wave-based control method has been shown to cope well with these challenges. The key idea is that the motion of the actuator can be separated into two notional components, one travelling from the actuator into the system, the other leaving the system through the actuator. Intuitively the actuator simultaneously launches mechanical waves into a system while it absorbs returning waves. When the launching and absorbing is finished vibrations have been damped and the desired reference motion is left behind. A mathematical model is developed for an upper stage accelerating rocket moving in a single plane. An equivalent mechanical model in the form of a pendulum is included to represent the fuel sloshing dynamics. In numerical simulations the controller successfully suppresses the sloshing motion. A major advantage of the strategy is that no measurement of the pendulum states (sloshing motion) is required. However it is found that when the effective sloshing mass becomes small relative to the rocket body, it takes longer to fully suppress sloshing motions. This is acceptable, however, because in this case, by definition, the sloshing does not cause a major problem for the rocket controller.

Keywords: Spacecraft Dynamics, Attitude Control, Flexible Systems, Sloshing, Mechanical Waves

1 INTRODUCTION

The failure of an early Jupiter ballistic missile in 1957 was caused by the interaction of the control system and the sloshing liquid fuel on board [1]. The problem was originally solved by aluminium drink cans, which could be fitted into the fuel tank and which floated on the surface of the fuel. Their friction both against the walls of the tank and against each other damped out the fuel oscillations. This experience motivated the eventual solution to the problem, which was the addition of baffles to the tank walls. However baffles can only provide a certain level of damping of the liquid motion and can only be optimized for one tank fill level, so their effectiveness is reduced as the propellant is depleted. They also add complexity and mass to the vehicle and so increase costs. [2]. It therefore becomes necessary to design a control system for a rocket which actively takes into account the effects of propellant sloshing and tries to compensate for them. Many mechanical systems are inherently flexible, making it difficult to achieve rapid, controlled motion. The control challenge is even greater when the system is not well modelled, has dynamics that change with time, or is under-actuated. A rocket with sloshing fluid propellant on board is an extreme case of such a system. A wave-based control method has been shown to cope well with the challenges outlined above [3, 4]. The key idea is that the motion of the actuator can be separated into two notional components, one travelling from the actuator into the system, the other leaving the system through the actuator. Intuitively the actuator simultaneously launches mechanical waves into a system while it absorbs returning waves. When the launching and absorbing is finished, vibrations
have been damped and the desired reference motion is left behind. The method has been demonstrated to work well for 1-D and 2-D lumped flexible systems and in robotic and crane applications [5, 6]. The aim of this paper is to extend the application to the control of spacecraft with flexible structures and appendages (e.g. solar panels), and with on-board liquid propellant. This new area of application presents many new challenges. The spacecraft systems are often nonlinear, their associated flexibility is non-uniform, the sloshing dynamics are difficult or impossible to predict, and sensors and actuators can behave far from the ideal. In this paper the example of an accelerating upper stage rocket is examined. A wave-based controller is designed for the upper stage AVUM of the European launcher Vega and is tested by numerical simulation.

2 MATHEMATICAL MODEL

In this section a mathematical model is developed for an upper stage accelerating rocket moving in a single plane. The rocket is assumed to be in a microgravity environment and free from aerodynamic effects. The sloshing fuel mass is represented by a mechanical analog in the form of a simple pendulum attached to the main rocket body. The fuel mass is partitioned, according to the tank fill level, into a fixed point mass and moving pendulum mass [7].

2.1 Planar upper stage model

The model of the upper stage rocket with single pendulum is shown in figure 1.

![Figure 1. Upper stage rocket model](image)

The rocket body and pendulum are isolated and free body diagrams for each are shown in figure 3.

![Figure 2. Free body diagrams](image)

The equations of motion for the two bodies may be written as:

\[
F - R_x = ma_x
\]  

(1)
where again actuated by lateral thrusters as shown in figure 3(b). In this case:

\[ f - R_z = ma_z \]  
\[ I \ddot{\theta} = M + b(R_z) \]

\[ R_x \sin \phi + R_x \cos \phi = 0 \]

\[ m_f[\dot{a}_z - b \dot{\theta}^2 + a \cos \phi (\dot{\theta} + \dot{\phi})^2 + a \sin \phi (\dot{\theta} + \dot{\phi})] = R_x \]

\[ m_f[\dot{a}_z - b \dot{\theta} - a \sin \phi (\dot{\theta} + \dot{\phi})^2 + a \cos \phi (\dot{\theta} + \dot{\phi})] = R_z \]

All symbols are described in table 1.

<table>
<thead>

</tbody>
</table>

Substituting for \(R_x\) and \(R_z\) from equations 5 and 6 into equations 1-4 eliminates these internal constraint forces, and gives a minimal set of four equations for the four degree of freedom system.

\[ (m + m_f) a_x - m_f b \dot{\theta}^2 + m_f a \cos \phi (\dot{\theta} + \dot{\phi})^2 + m_f a \sin \phi (\dot{\theta} + \dot{\phi}) = F \]

\[ (m + m_f) a_z - m_f b \dot{\theta} - m_f a \sin \phi (\dot{\theta} + \dot{\phi})^2 + m_f a \cos \phi (\dot{\theta} + \dot{\phi}) = f \]

\[ (l + m_f b^2) \ddot{\theta} - m_f b a_x + m_f a b \sin \phi (\dot{\theta} + \dot{\phi})^2 - m_f a b \cos \phi (\dot{\theta} + \dot{\phi}) = M \]

\[ (m_f a^2) (\dot{\theta} + \dot{\phi}) - m_f a b \sin \phi \dot{\theta}^2 - m_f a b \cos \phi \dot{\phi} + m_f a (a_c \cos \phi + a_z \sin \phi) = 0 \]

### 2.2 Choice of actuators

The model described is general in that the body is actuated by two forces, \(F\) and \(f\), and a moment, \(M\). In reality the rocket may have one or many actuators, but in any configuration these actuators may be resolved to these two forces, axial and lateral, and a moment applied to the rocket body. In some cases these inputs may not be independent of each other, but instead a function of some lesser number of inputs. For example, in the case of a rocket as shown in figure 3(a) with a single gimbaled engine the forces and moment are no longer independent and are given by:

\[ M = T(b + c) \sin \delta, \quad F = T \cos \delta, \quad f = T \sin \delta \]

where \(T\) is the constant thrust developed by the rocket engine, \(c\) is the distance of the gimbal from the mass centre, and the single input is the engine gimbal angle \(\delta\). Similiarly the rocket may be actuated by lateral thrusters as shown in figure 3(b). In this case:

\[ M = Td, \quad F = T, \quad f = T_l \]

where again \(T\) is the constant thrust developed by the non-gimballing rocket engine, \(d\) is the axial distance from the thrusters to the mass centre, and the single input is the magnitude of the lateral thrust \(T_l\).
### 2.3 Linearized model

Solving equations 7 and 8 for \( a_x \) and \( a_z \) respectively gives:

\[
a_x = \frac{F + m_f b \dot{\theta}^2 - m_f a \cos(\dot{\phi} + \phi)^2 - m_f a \sin(\dot{\phi} + \phi)}{m + m_f}
\]  
(13)

\[
a_z = \frac{f + m_f b \dot{\phi} + m_f a \sin(\dot{\phi} + \phi)^2 - m_f a \cos(\dot{\phi} + \phi)}{m + m_f}
\]  
(14)

Substituting these expressions into equations 9 and 10 gives a simplified system of two equations describing the pitch and slosh dynamics:

\[
[I + mm^*(b^2 - ab \cos \phi)] \ddot{\theta} - mm^* ab \ddot{\phi} \cos \phi + mm^* ab (\dot{\theta} + \dot{\phi})^2 \sin \phi = M + m^* b f
\]  
(15)

\[
m^* (a^2 - ab \cos \phi) \ddot{\theta} + mm^* a^2 \ddot{\phi} + m^* (a F - mab \dot{\theta}^2) \sin \phi = m^* a f \cos \phi
\]  
(16)

where:

\[
m^* = \frac{m_f}{m + m_f}
\]  
(17)

After linearization about \([\theta, \phi, \dot{\theta}, \dot{\phi}] = 0\) equations 15 and 16 become:

\[
[I + mm^*(b^2 - ab)] \ddot{\theta} - mm^* ab \ddot{\phi} = M + m^* b f
\]  
(18)

\[
m^* (a^2 - ab) \ddot{\theta} + mm^* a^2 \ddot{\phi} + m^* a F \phi = m^* a f
\]  
(19)

The state vector of the linearized system consists of the pitch and slosh angles and their derivatives:

\[
x = [\theta, \phi, \dot{\theta}, \dot{\phi}]^T
\]  
(20)

It is assumed that the axial thrust \( F \) is a constant, so that the input vector consists of the lateral force and moment \( M \):

\[
u = [f, M]^T
\]  
(21)

Now equations 18 and 19 may be rewritten in state space form:

\[\dot{x} = Ax + Bu\]  
(22)

where:

\[
A = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & \frac{F b m_f}{(m + m_f)} & 0 \\ 0 & \frac{F m_f (b^2 - ab)}{I a (m + m_f)} & -\frac{F a}{I a} & 0 \\ \end{bmatrix}, \quad B = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & \frac{1}{I a} \\ \frac{(b - a)}{I a} \\ \end{bmatrix}
\]  
(23)
We find that the condition for stability of this linearized system is:

\[
\frac{nmf(b^2 - ab)}{m + mf} + I \geq 0 \quad (24)
\]

Possible pendulum configurations are shown in figure 4. For \( b < 0 \) (pendulum pivot point behind the mass centre) (figure 4(a)) or \( b > a \) (whole pendulum in front of mass centre) (figure 4(b)) this condition is always satisfied, but in the region \( 0 < b < a \) stability is achieved only if:

\[
a - b \geq \frac{I(m + mf)}{bmmf} \quad (25)
\]

Physically this means that the pendulum must straddle the point P shown in figure 4(c) which is a distance \(-\frac{I(m + mf)}{bmmf}\) from the centre of mass along the x-axis.

3 WAVE-BASED MODEL

The first step in developing a wave model for the rocket system is to express the equations of motion in a form resembling a cascaded lumped flexible system. The rocket system described by equation 22 has two degrees of freedom and so it is required to transform this to appear like a 2-DOF lumped flexible system, i.e two masses/inertias with an interconnecting spring. It is also required that there be a single control input which actuates just the first degree-of-freedom, i.e. a single launcher and absorber of waves. The system should have the following form:

\[
\dot{z} = \hat{A}z + \hat{B}f_0
\]

where:

\[
\hat{A} = \begin{bmatrix}
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
-k_1 m_1 & k_1 m_1 & 0 & 0 \\
k_2 m_2 & -k_2 m_2 & 0 & 0
\end{bmatrix}, \quad \hat{B} = \begin{bmatrix}
0 \\
0 \\
\frac{1}{m_1} \\
0
\end{bmatrix}, \quad z = \begin{bmatrix}
x_1 \\
x_2 \\
x_1' \\
x_2'
\end{bmatrix}
\]

These equations describe the dynamics of a 2-DOF mass-spring system, where \( x_1 \) and \( x_2 \) are the displacements of the masses and \( f_{act} \) is the actuating force on the first mass. Assume that the lateral force \( f \) on the rocket body is zero and just the pure moment \( M \) is available for control purposes. In reality this could be imagined as a gimballed rocket engine with lateral thrusters at mass centre to cancel the lateral forces from the engine. The input matrix \( B \) from equation 23 then becomes a
column vector:

\[
B = \begin{bmatrix}
0 \\
0 \\
\frac{1}{a-b} \\
\frac{b-a}{ia}
\end{bmatrix}
\]  

(28)

To transform the system to the required form the change of basis \(z = Mx\) is used, where:

\[
M = \begin{bmatrix}
1 & 0 & 0 & 0 \\
1 & \frac{a}{a-b} & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 1 & \frac{a}{a-b}
\end{bmatrix}, \quad \hat{A} = MAM^{-1}, \quad \hat{B} = MB
\]  

(29)

The states are now:

\[x_1 = \theta, \quad x_2 = \theta + \left(\frac{a}{a-b}\right)\phi \]  

(30)

and the parameters of the system are given by:

\[k_1 = \frac{F bm_f(a-b)}{a(m+m_f)}, \quad m_1 = I, \quad m_2 = \frac{mm_f(b^2-ab)}{m+m_f}\]  

(31)

Figure 5 shows the equivalent mass-spring system with a notional mass \(m_0\) and notional spring of stiffness \(k_0\) appended to the system. The force in the first spring is considered to be the actuation force \(f_1\). The system may now be considered as actuated by the displacement \(x_0\) of notional mass \(m_0\) such that:

\[f_0 = k_0(x_0 - x_1)\]  

(32)

The wave model assumes that the displacement of each mass \(x_i\) is can be seperated into leftward and rightward travelling components \(a_i\) and \(b_i\) respectively or \(A_i\) and \(B_i\) in the Laplace (complex frequency) domain [8]. The propagation of the rightward and leftward travelling waves is described by wave transfer functions \(G_i, H_i\) and \(F\) respectively such that:

\[A_i = G_{i-1}A_{i-1}, \quad B_i = H_{i+1}B_{i+1}, \quad B_2 = FA_2\]  

(33)

For controller design it is easier to work with transfer functions that deal with the actuating force \(F_0\) rather than the notional displacement \(X_0\). The spring force \(F_0\) can also be seperated into rightwards and leftwards travelling components \(F_0A\) and \(F_0B\) respectively. Then the cross-over wave transfer functions \(P_0\) and \(Q_0\) relate displacements to forces by:

\[A_1 = P_0F_0A, \quad F_0B = Q_0B_1\]  

(34)

and these can be calculated from the ordinary wave transfer functions as:

\[P_0 = \frac{G_0}{k_0(1-G_0)^2}, \quad Q_0 = k_0(H_0 - 1)\]  

(35)

4 CONTROL DESIGN

4.1 Wave-Based Controller

A WBC3 (force actuated) controller was designed to control the rocket attitude \(\theta\). The controller uses only the transfer functions \(G_0\) and \(H_0\). The second-order uniform system approximations [8] are used where:

\[G_0 = \frac{\omega_G^2}{s^2 + \omega_Gs + \omega_G^2}, \quad \omega_G = \sqrt{\frac{2k_0}{m_1}}\]  

(36)
The wave-based control scheme is shown in figure 6. $\theta_{ref}$ is the desired reference pitch angle. The control input is the input torque $M_{ref}$. Two variables are measured for feedback. These are the pitch angle $\theta$ and the actual achieved torque $M$. In this paper the actuator is assumed ideal except for the saturation limits. The wave based control strategy launches a wave equal to half the reference signal $\theta_{ref}$. The measured values of $\theta$ and $M$ are then used to calculate the returning wave component at the actuator which can be calculated as:

$$B_0 = H_0 \left( \frac{\theta - P_0 M}{1 - P_0 Q_0} \right)$$

The actuator is then moved to match this returning wave component and thereby absorb it. When the absorbing is finished the system will have been displaced by twice the specified launch wave, i.e. will be at the reference displacement.

### 4.2 Time-Optimal Controller

For comparison, the torque-limited bang-bang solution for a rest-to-rest maneuver of a rigid rocket was calculated. With the slosh pendulum frozen in position the moment of inertia of the rocket body about the overall mass centre is given by:

$$I_{rigid} = I + \frac{mm_f(b-a)^2}{(m+m_f)}$$

(39)
The switching time for a rest to rest maneuver is:

\[ t_s = \sqrt{\frac{\theta_{ref} f_{rigid}}{M_{\text{max}}}} \]  

(40)

where \( M_{\text{max}} \) is the maximum torque. Then the control input for the bang-bang maneuver beginning at \( t = t_0 \) is:

\[
M = \begin{cases} 
0 & t < t_0 \\
M_{\text{max}} & t_0 < t < t_0 + t_s \\
-M_{\text{max}} & t_s < t < t_0 + 2t_s \\
0 & t > t_0 + 2t_s 
\end{cases}
\]  

(41)

5 RESULTS

6 Simulation of a real rocket

The wave-based controller was tested by numerical simulation. Suitable parameters for the presented rocket model were chosen to represent AVUM, upper stage of the European Vega launcher [9] (table 2). The included slosh pendulum represents the primary sloshing mode for the rocket’s fuel tank when half full. The saturation torque \( M_{\text{max}} \) was calculated from the maximum gimbal angle of the AVUM engine. The values chosen for notional mass and spring stiffness were \( m_0 = m_1 \) and \( k_0 = k_1 \ast (m_1/m_2) \), however the choice for these parameters is arbitrary to some degree and a range of values will give a good control response. Results are shown in figure 7 for a five degree step change in commanded pitch angle \( \theta_{ref} \). The wave-based controller is compared to the torque-limited time-optimal solution for the rigidized rocket.

7 DISCUSSION

It can be seen that the fuel slosh dynamics cause the open-loop time optimal controller to land off target and drift away from the target over time. The fuel sloshing persists for long times in the absence of damping in the model. The wave-based controller lands on target and suppresses the sloshing motion. However the sloshing persists for several oscillations. The reason for this is the non-uniformity of the system, i.e. unequal inertias \( m_1 \) and \( m_2 \). In this case \( m_1 \) is much less than \( m_2 \). From a wave perspective there is a change in wave impedance between the two different masses and some waves become trapped on the right hand side of this boundary. For this reason the actuator only absorbs a fraction of the motion on each oscillation cycle, but over several cycles can absorb it all. When the ratio of inertias \( \frac{m_1}{m_2} \) is much less than one, the effect of the pendulum on the body is much reduced and so it takes longer to fully suppress sloshing motions. This is acceptable, however, because in this case, by definition, the sloshing does not cause a major problem for the rocket controller. On the other hand, the control challenge is greatest when the fluid inertia ratio is large, and this is precisely when the new strategy delivers much
improved performance. An interesting avenue of future research is developing wave-models and controllers which take into account the non-uniformity of the system to be controlled. A clear advantage of wave-based control is that all measuring is done at the actuator, in this case the rocket body, so no measurement of the pendulum states is necessary, which is a significant bonus given the challenge of measuring or modelling them in a real rocket. Future research includes making the controller robust to external disturbances such as aerodynamic, stage separation or gravity forces; considering non-ideal actuator and sensor behaviour; including multiple slosh pendulums representing either multiple fuel tanks or multiple modes of sloshing in a single tank; and extending the analysis to a 6-DOF model where roll, pitch and yaw must be simultaneously controlled.
